

# By Any Means Necessary: Multiple Avenues of Political Cycles

Andrew Philips

2014 EITM Summer Institute  
University of Houston

June 22, 2014

- Are Political Budget Cycles (PBCs) the only “tool” an incumbent strategically uses for electoral gain?
- Is the *passage* of redistributive policies an adequate signal to voters of an incumbent's competency?

- Opportunistic Political Business Cycles.
  - $\pi$  vs. unemployment  $\rightarrow$  Phillips curve
  - Adaptive expectations (voters can be fooled)
  - (Nordhaus 1975; Lindbeck 1976; Tufte 1978)
- Partisan Political Business Cycles
  - Hibbs' (1977) response to opportunism
  - Ideological priorities on where spending should go
  - Still adaptive expectations
- Rational Expectations (Rogoff and Siebert 1988; Rogoff 1990)
  - Incumbent *signals* to voters of competency
  - Asymmetric information replaces irrationality

- Political Budget Cycles
  - Move towards developing countries (Brender & Drazen 2005)
  - Taxes decrease, Spending on public services increase (Khemani 2004)
  - Transfers occur just before elections; decrease after elections (Akhmedov & Zhuravaskaya 2004)
- “Conditional” Political Cycles
  - Ideology: left-wing parties spend more (Veiga & Veiga 2007)
  - Competition: spend only if competition is intense (Chhibber & Nooruddin 2004)
  - Visibility: Spending on roads & infrastructure (Drazen & Elsavva 2010)
  - Targeting: Spend only in regions you need to win/may lose (Aidt et al. 2011)

Non-budgetary areas that also exhibit some political manipulation/temporal component...distribution and timing

- Lending to farmers, loan forgiveness (Cole 2009)
- Timing of avoidable wars (Hess & Orphanides 1995)
- Bureaucratic approval of environmental licenses (Ferraz 2007)
- Prices and output of politically-connected sugar mills (Sukhtankar 2012)

- Does the *passage* of distributive policies exhibit cyclical properties like spending (i.e. timed around elections)?

The passage of policies used to redistribute/target/reward voters is timed strategically; politicians will use these policies as a *visible* component to win voter support before an election.

- Efficiency: Affect large swaths of voters (esp. dev. countries)
- Bypass spending constraints
- Signal of competency
- More palpable to voters than campaign promises
- Advantageously time what would have happened anyway

Unifying theoretical and applied statistical concepts:

- Theoretical Concept → **Decision-making**: does the incumbent pass a redistributive policy strategically?
- Statistical Concept → **Nominal choice**: Incumbent can either pass a policy, or not.

Develop Behavioral and Applied Statistical Analogues:

- Behavioral Concept → **Utility maximization:**
  - Voter wants to maximize utility across time through vote choice
  - Incumbent tries to maximize utility through policy and spending
  - Some **Conditional expectations**...discount the future
  - Also some **Uncertainty** about economic conditions
- Statistical Concept → **Binomial choice:** Is a redistributive policy passed in region  $i$  in year  $t$ ?

## Unify and Evaluate the Analogues:

- Linkage between the two: In order to maximize their utility, incumbents will time redistributive policy to occur before the election.
  - Less likely when incumbent can shift spending towards areas visible to voters (PBC)
  - More likely when incumbent must “pull out all the stops” ...e.g. when the economy is poorly performing

- Two-period game  $t \in \{1, 2\}$ ; Election after  $t = 1$
- Two types of voters  $V \in \{R, P\}$ , always more poor than rich
  - 1 Poor, of proportion  $n$  where  $n > 0.50$
  - 2 Rich, of proportion  $1 - n$
- Two citizen-politicians  $A$ 
  - 1 Incumbent,  $A = I$
  - 2 Challenger,  $A = C$

- Reputation
  - Or quality/legacy/skill...

$$\epsilon^I \in \{\underline{\epsilon}^I, \overline{\epsilon}^I\} \quad (1)$$

- Common knowledge based off the previous performance of the incumbent in office.

- Reputation/skill matters for supplying general public good:

$$\sum_{j=1}^N g_t = \sum_{j=1}^N \tau + \epsilon^j \quad (2)$$

- $\tau$  is flat tax, given exogenously
- $\uparrow \epsilon^j$  will  $\uparrow g_t$ , ceteris paribus
- Can also pass redistributive policy  $\zeta_t$ 
  - $U_t^{j,R} = -\zeta_t$
  - $U_t^{j,P} = \gamma \zeta_t$
- Entire cost paid by rich
- Redistributive policy benefits the poor
- Discount  $\gamma \in [0, 1]$ 
  - Accounts for credibility ( $\uparrow \gamma$ ,  $\uparrow$  credibility)
  - Deadweight loss

- Relative economic advantage,  $\alpha_t$
- Drawn each time period
- Function of average incumbent advantage and a i.i.d. stochastic shock,  $\eta_t$  with mean zero

$$\alpha_t = \bar{\alpha} - \eta_t \quad (3)$$

where  $\eta_t = (\eta_t^{Expectation} - \eta_t^{Actual})$

- Incumbent knows  $\bar{\alpha}$ , not  $\alpha_t$ 
  - More risk-averse incumbent may assume lower  $\bar{\alpha}$

- Time  $t = 1$ 
  - 1 Everyone observes  $\epsilon'$ , the incumbent's skill/legacy/reputation. Incumbent forms  $\bar{\alpha}$  based off prior economic information.
  - 2 Incumbent decides on government spending and if he will pass policy
  - 3 Voters observe government spending and the signal of the policy that is passed.
  - 4 Everyone observes  $\alpha_t$
  - 5 Incumbent runs against citizen-voter challenger. If  $> 1/2$  of voters support him, incumbent remains in office
- Time  $t = 2$ 
  - 1 The incumbent (if re-elected), spends on government goods.
  - 2 If land reform has not been passed, the incumbent has the option to pass it.

$$W^{j,v} = U_1^{j,V}(I) + \rho(U_2^{j,V}(A)) \quad (4)$$

where

$$U_1^{j,R}(I) = y_1 - \tau + \ln(\tau + \epsilon^I) + \alpha_1 - \zeta \quad (5)$$

$$U_1^{j,P}(I) = y_1 - \tau + \ln(\tau + \epsilon^I) + \alpha_1 + \gamma\zeta \quad (6)$$

- $W^{j,v}$ : Present expected util.
- $U_1^{j,V}(I)$ : Util. in  $t = 1$  under incumbent for type  $V$
- $\ln(\tau + \epsilon^I) = \ln(g_t)$ ..Note decreasing returns
- $\rho(U_2^{j,V}(A))$ : Discounted util. in  $t = 2$  for type  $V$  under politician  $A$
- $y_t =$  non-storable income

Vote for incumbent if:

$$U_1^{j,V}(I) + \rho(U_2^{j,V}(I)) - \rho(U_2^{j,V}(C)) > 0 \quad (7)$$

In each period:

$$\Omega_t^I = nW^{j,P} + (1 - n)W^{j,R} + D\chi \quad (8)$$

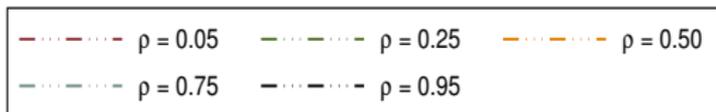

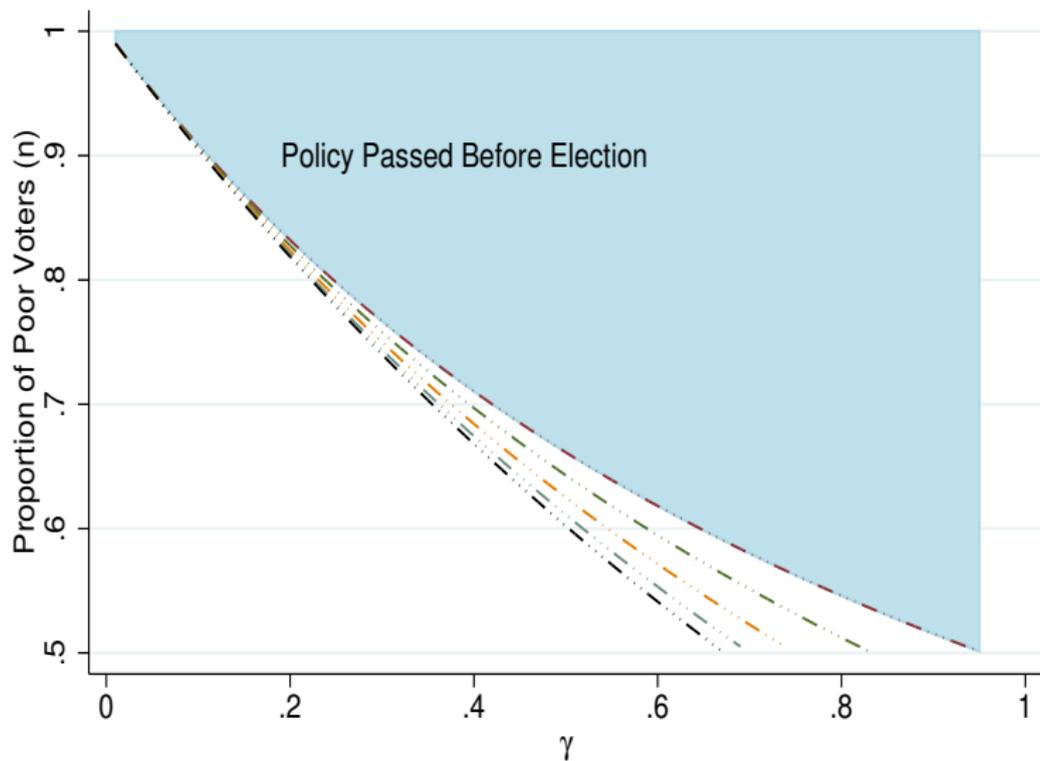

- $\Omega_t^I$ : Incumbent utility
- “rents” / “desks” given by  $\chi$
- $D =$  dummy variable = 1 if incumbent is in government

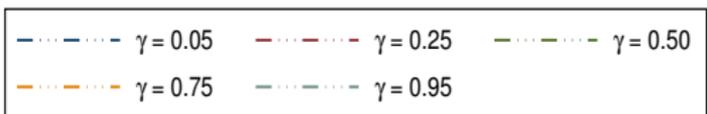

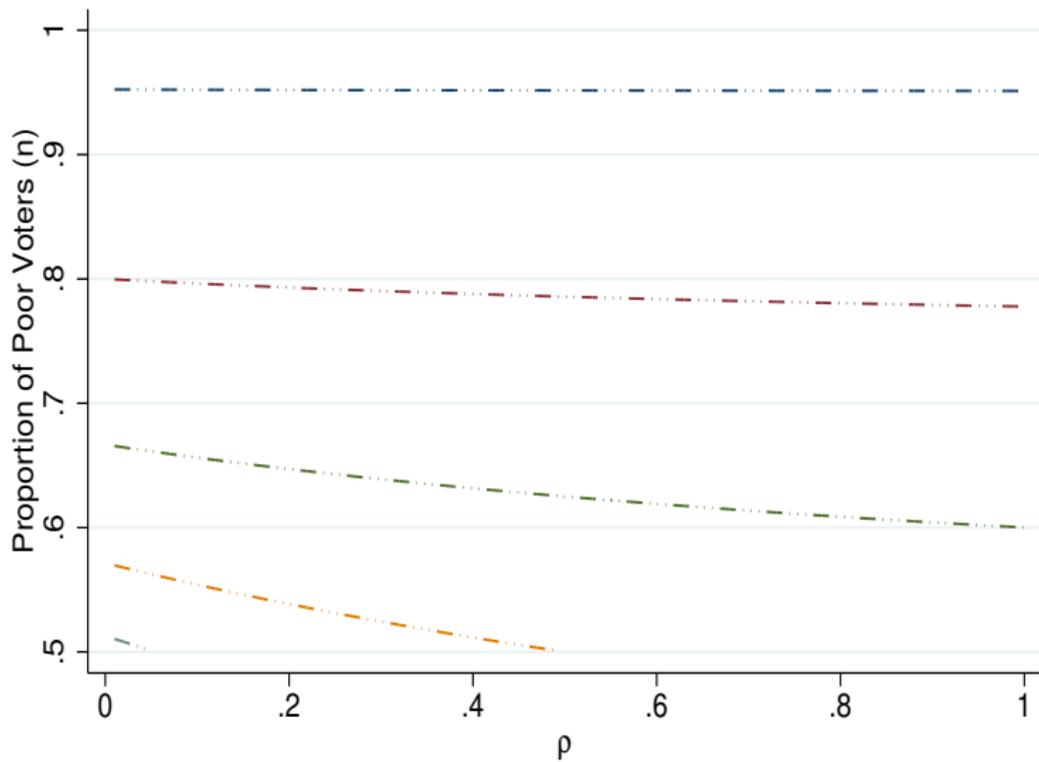

**An incumbent gains more from passing a policy before an election than not passing, or passing it after**

$$E[\Omega'_{t,Passage}] > E[\Omega'_{t,No Passage}] \quad (9)$$

simplified to:

$$n > \frac{1 + \rho(1 - \gamma)}{\gamma + 1 + \rho} \quad (10)$$

**Passing a policy serves as a substitute to government spending**

$$\max_{g_t} E[\Omega'_{Passage}] > \max_{g_t} E[\Omega'_{NoPassage}] \quad (11)$$

But..... end up with  $\frac{1}{g_t} > \frac{1}{g_t}$

- How to take into account policy passage?
- Some tradeoff ( $\frac{\zeta}{g_t}$ )? Use  $\zeta$  and  $g_t$  to make a constraint function?

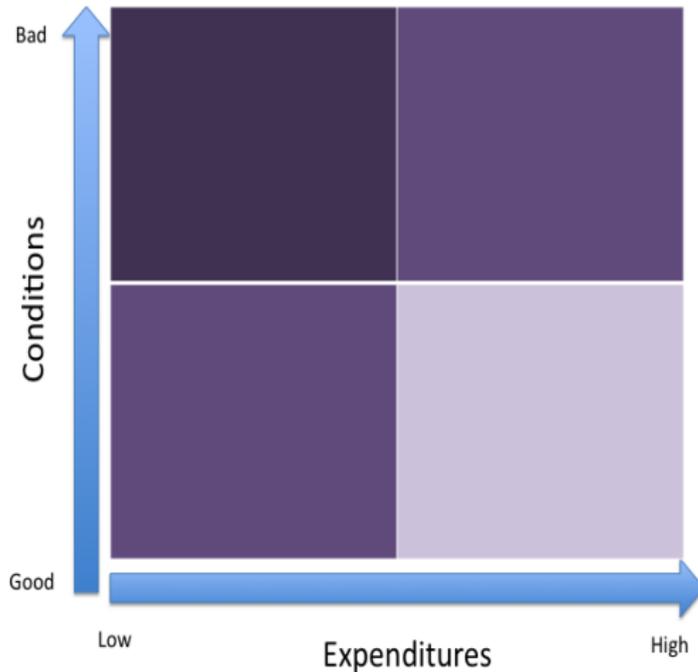

**When the economy is especially bad, an incumbent may use both strategic policy passage and government spending to win the election**

- How to take into account  $\alpha$  while simultaneously addressing issue in Proposition II?

Increasing complexity of the propositions:

- $H_1$  **Simple:** Policies are timed to occur before an election → Public Policy Cycle
- $H_2$  **Substitutes:** More traditional political business cycle spending ( $g_t$ ) means lower likelihood of public policy cycle
- $H_3$  **Conditional Substitution:** Pre-election conditions ( $\alpha$ ) may interact to affect the relationship between both
  - Substitute effect *only* occurs when conditions are good
  - In bad conditions, incumbent pursues *any* and *all* channels of manipulation
  - Conditions → economic, expected competition, public support...

Figure 1 : Darker color → greater Pr(policy cycle)

*...giving land is like parting with your soul or body. People are more attached to land than anything*

—Governor of Karnataka, 1976

How is Indian land reform an ideal candidate for political policy cycles?

- Reforms delegated to states
- Indian state elections *most* important type
  - Staggered state elections
  - Must be held every 5 years
  - Highest voter turnout during state elections
  - Local government largely inactive during this period (1957–1992)
- Large variation within a single developing country
- Visible policy, appeals directly to certain constituencies
  - Past history of land inequality
  - Popular movements for reform after Independence

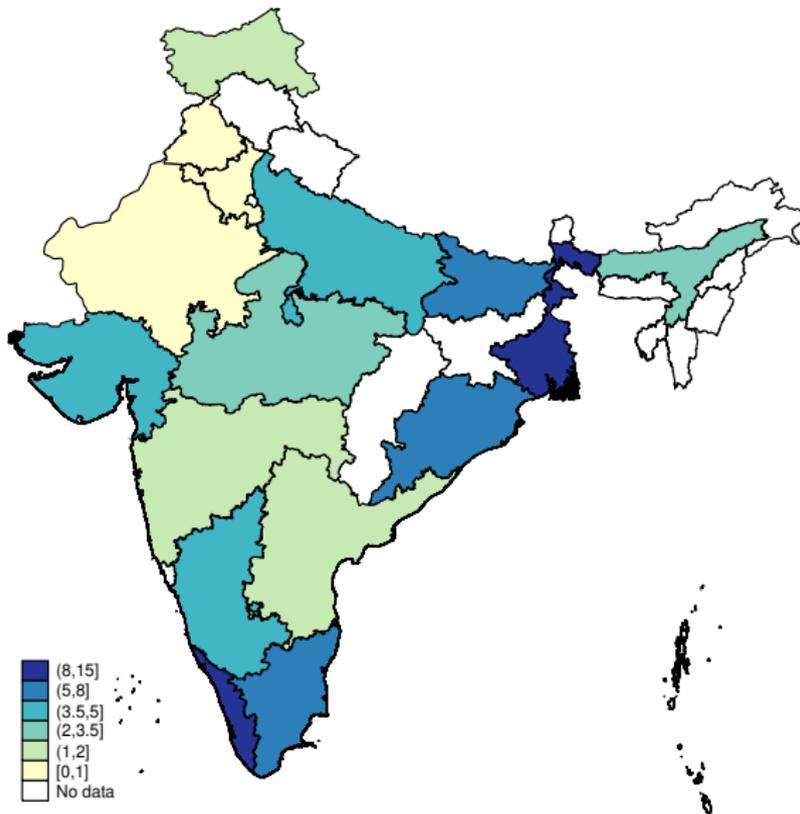

Figure 2 : Number of Land Reforms, 1957-1992

$$Pr(LandReform_{i,t} \neq 0 | \pi_{i,t}) = f(\text{Elections} + \text{PBC Spending} + \text{Economic Conditions} + (\text{Elections} * \text{PBC Spending} * \text{Economic Conditions})) \quad (12)$$

- Panel logit with RE (15 states, 1957–1992)
- $\zeta = \text{Land Reform}_{i,t}$
- Election: If state  $i$  is holding an election in year  $t - s$  where  $s \in [-2, -1, 0, 1, ]$
- $\alpha = \text{Inflation}_{t-1}, \Delta \text{GSP}_{t-1}$  per capita
- $n \approx \text{Land GINI}$
- $g_t = \text{Development Expenditures}$
- $\gamma = \text{Past land reforms (\& squared)}$
- $\epsilon^l = \text{GSP}_{t-1}$
- Controls: (Ideology, Eff. # Parties, Early elections)
- Data Sources: Besley & Burgess 2000, 2002, 2004; Chhibber & Nooruddin 2004

Dependent variable is land reform. Random-effects logit with standard errors in parentheses.

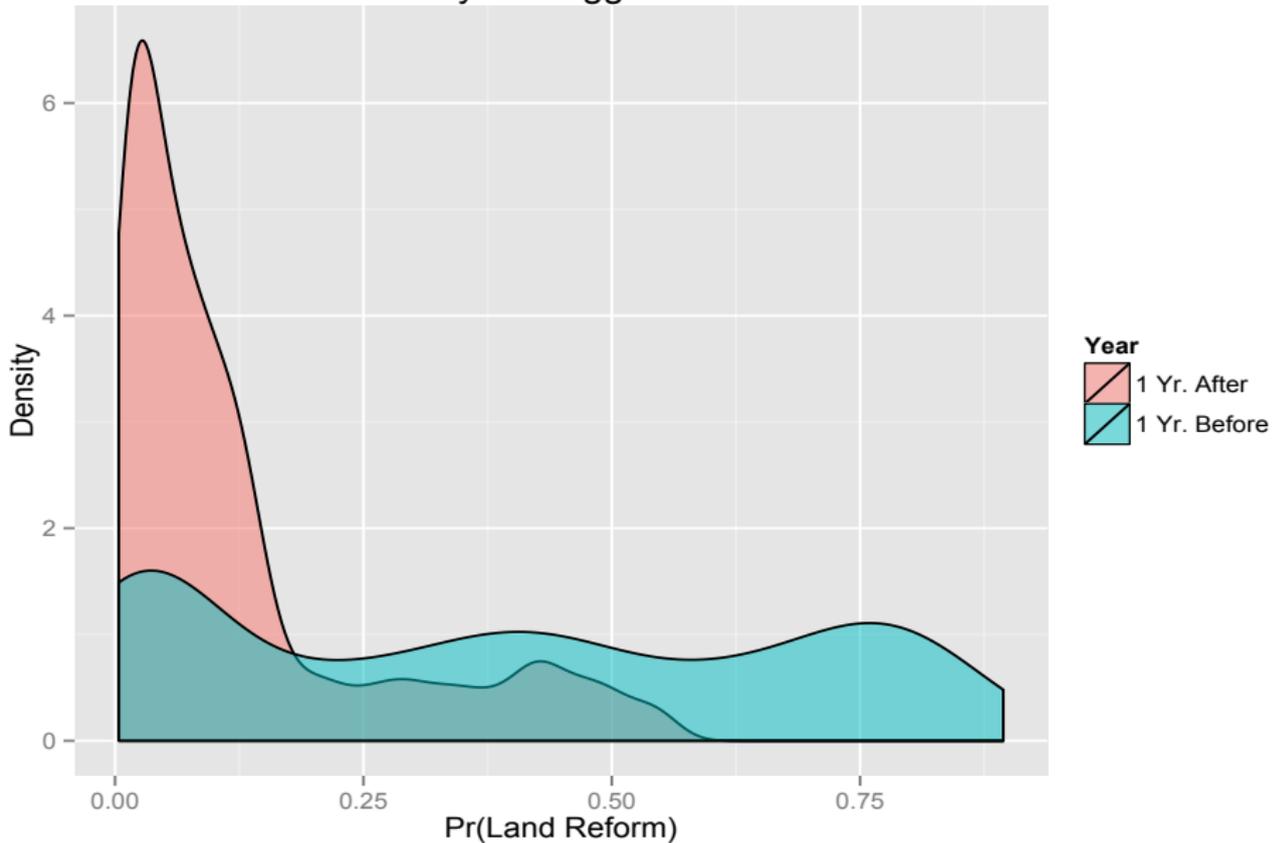

Log-odds coefficients reported with two-tailed tests on 15 Indian States. \*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

- Use models 4 (inflation) and 5 ( $\Delta$  in  $GSP_{t-1}$ )
- Simulate  $\Pr(\text{land reform})$  (+/-) 3 std. dev. of all possible pairwise combinations of economic conditions and budget spending across each year relative to the election
- Controls set to mean or modal category
- Simulations using CLARIFY (Tomz, Wittenberg, and King 2001)
  - Draws of parameters according to asymptotic sampling distribution

# K-Density for Lagged Change in GSP

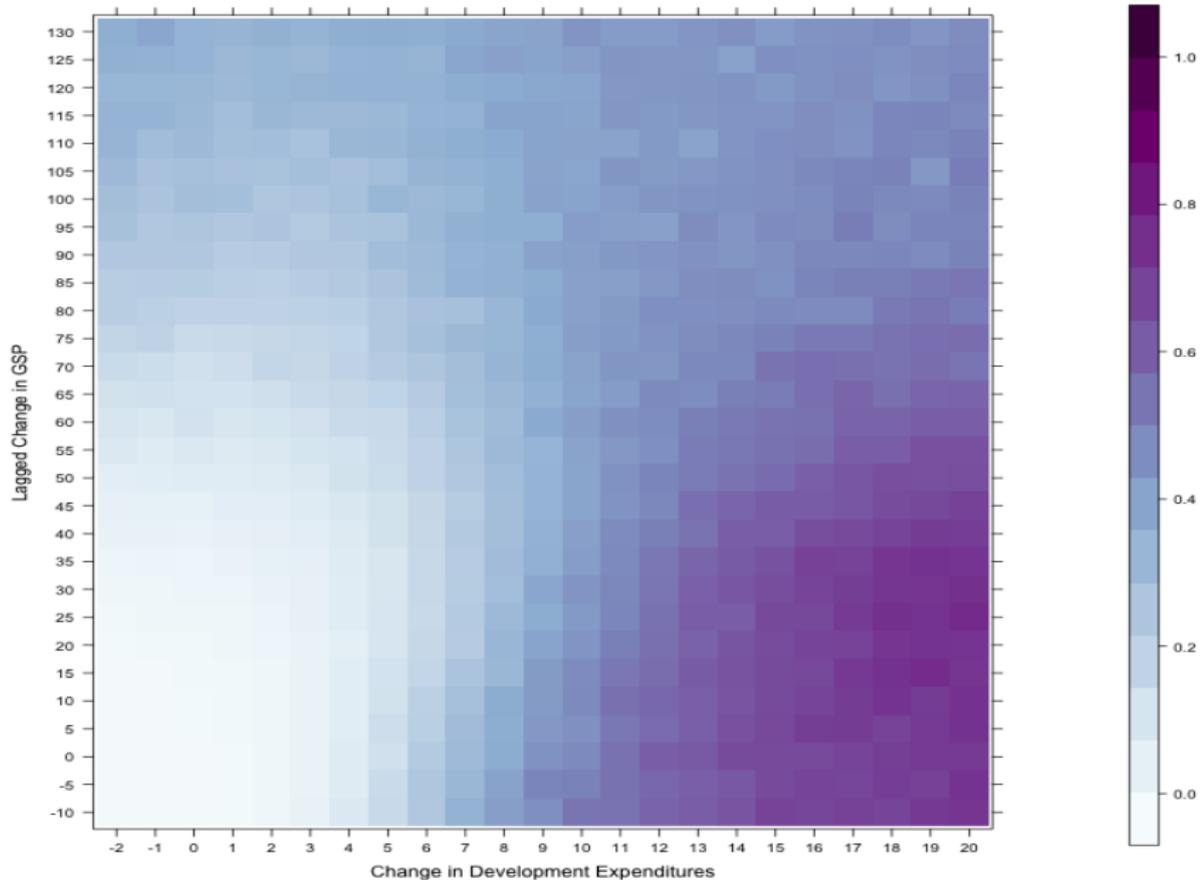

# K-Density for Lagged Inflation

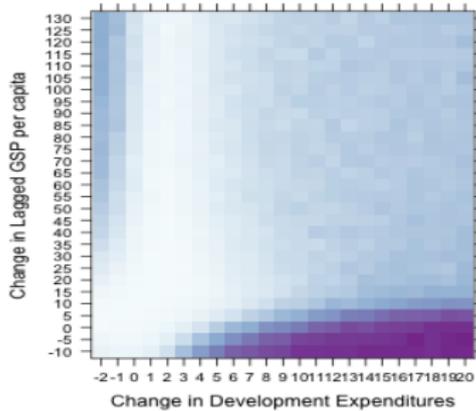

- Use results from simulation of predicted probability
- Interpretation
  - Vertical axis: Economic condition (inflation or GSP)
  - Horizontal axis:  $\Delta$  in Development expenditures ('00 Rs. per capita)
  - Colors:  $\uparrow$  purple  $\uparrow$  Pr(land reform)

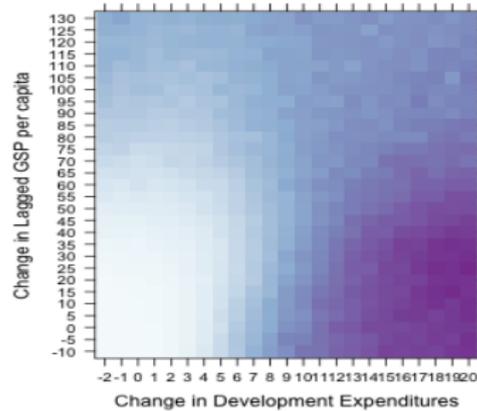

# 1 Year Before Election

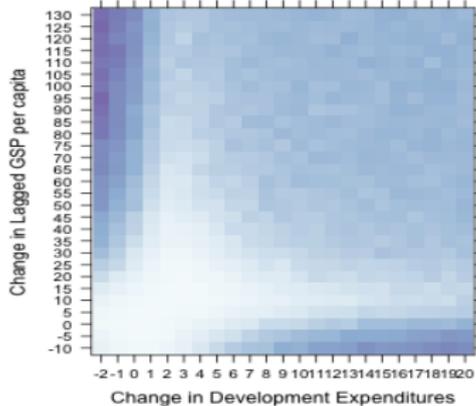

**2 Years Before Election**

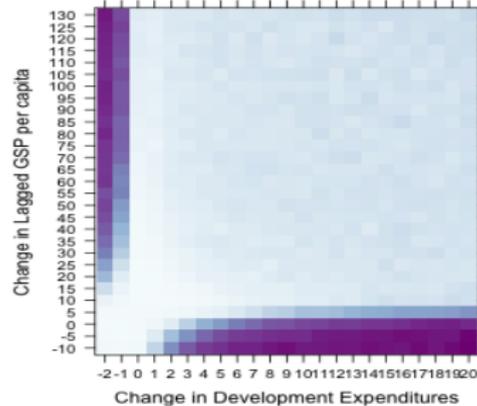

**1 Year Before Election**

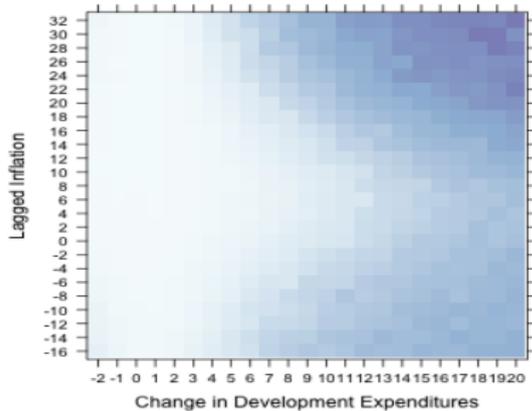

**Election Year**

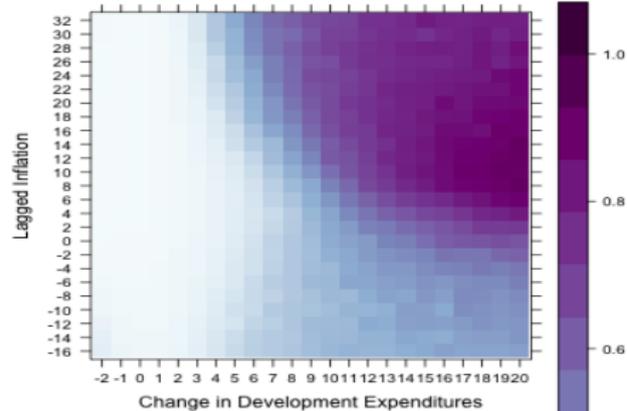

**1 Year After Election**

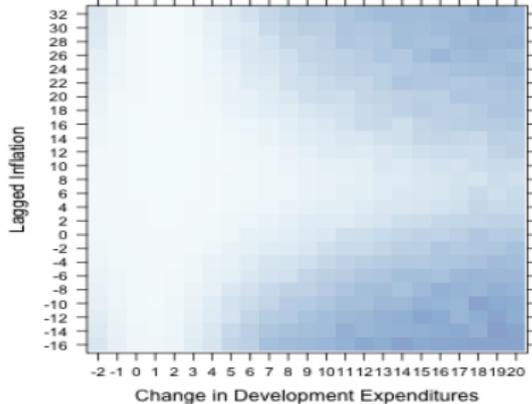

**2 Years Before Election**

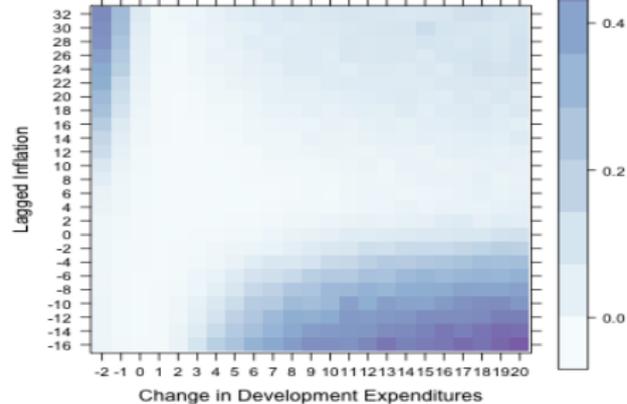

**1 Year Before Election**

**Election Year**

**1 Year After Election**

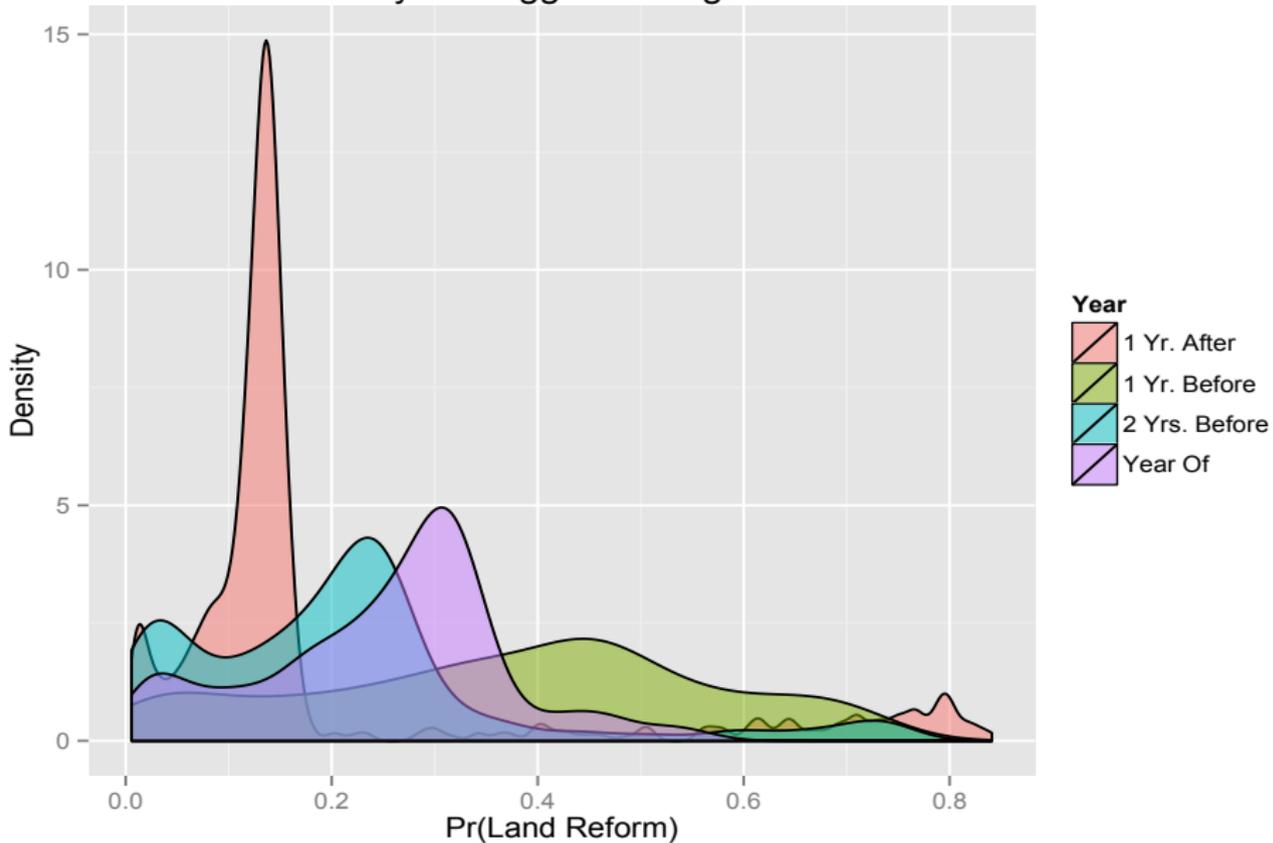

- 1 Modeling as “duration data” using cubic splines, time dummies.
  - Results even stronger
- 2 Spatial considerations (adjacent land reform in  $< 5$  years).
- 3 Examining inflation and GSP as lagged deviations from state means
- 4 Alternative spending measure of Education (which is encompassed in development spending), and Non-Development Expenditures.

- Formally showed why incumbents may strategically pass policy, especially if it can be used to win over large numbers of voters relatively inexpensively
- Empirical evidence that political policy cycles exist
- Some evidence that political policy cycles and PBCs are substitutes...
  - But that remains conditional on economic conditions
  - “Extreme” conditions make policy passage more likely, no matter what the level of spending is

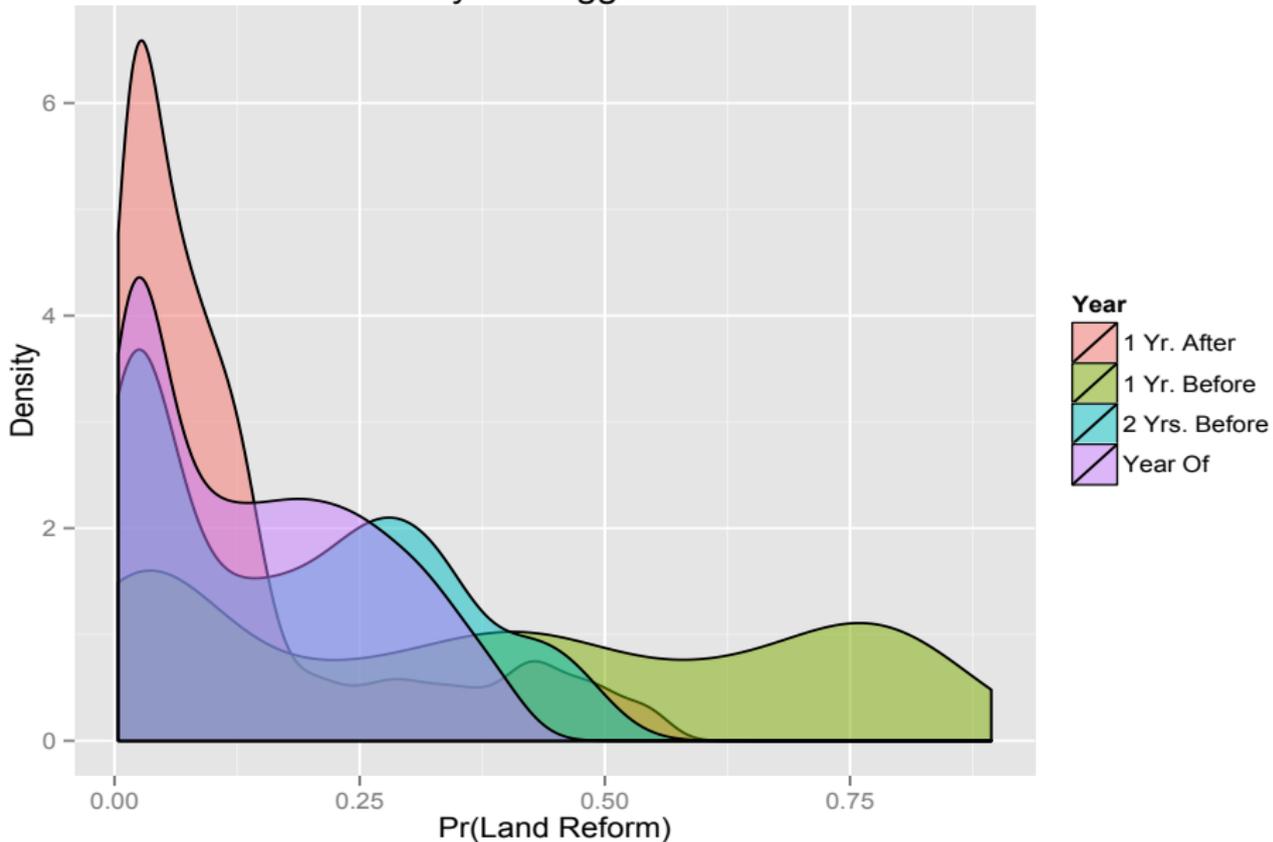

- Theoretical Model
  - Lots of work needed
  - Finish modeling Propositions II, and III
  - Add ideology? Not a big deal in this example
  - Incorporate early elections (another “tool”)
- Empirical Test
  - Instrument with rainfall (correlated with economic conditions, arguably not land reform)
  - Instrument early elections (Khemani 2004)
  - Showing significance on figures (ringed/dashed areas showing significance)....Or:
    - Investigate parameter shifts (i.e. marginal effects) rather than predicted probabilities
  - Use Franzese’s transformation to account for the month of election
  - Other controls? Robustness checks?
- Add a smoother transition between TM and EI

Thank You
