## Background

### What is Agent-based Modeling?

- ABM has been considered as a bottom-up approach modeling behaviors of a group of agents, rather than a representative agent, in a system.
- The representative-agent hypothesis allows for greater ease in solution procedures.
  - It is easier to find the equilibrium (relatively...).
  - This is usually called the analytical optimization.

## Background

### What is Agent-based Modeling?

- **Examples of the representative-agent models:**
  - Profit maximization, utility maximization, or cost/loss minimization...
- **Methods of optimization:**
  - (1) First-order condition - unconstrained optimization
  - (2) Lagrangian multiplier - constrained optimization
  - (3) Dynamic optimization
    - (a) Bellman equation (over discrete time), and
    - (b) Hamiltonian multiplier (over continuous time).

## Background

### What is Agent-based Modeling?

- LeBaron and Tesfatsion (2008, 246): "Potentially important real-world factors such as subsistence needs, incomplete markets, imperfect competition, inside money, strategic behavioral interactions, and open-ended learning that tremendously complicate analytical formulations are typically not incorporated"

## Background

### What is Agent-based Modeling?

- One important element of ABM is that it allows the possibility of agents' interactions in micro levels with the assumption of bounded-rationality or imperfect information.
- Given agents' heterogeneous characteristics and their interactions at the micro level, we can simulate the system and observe changes in the macro level over time according to the system-simulated data.

## Background

### Applications of ABM

- Poli. Sci.** (Bendor, Diermeier and Ting, APSR 2003; Fowler, JOP 2006)
  - BDT (2003):
    - A computational model by assuming that voters are adaptively rational — voters learn to vote or to stay home in a form of trial-and-error.
    - Voters are reinforced to repeat an action (e.g., vote) in the future given a successful outcome today.
    - The turnout rate is substantially higher than the predictions in rational choice models.
  - Fowler (2006):
    - He revises the BDT model by including habitual voting behavior.
    - Fowler finds his behavioral model is a better fit to the same data BDT use.

## Background

### Applications of ABM

- Economics**
  - Econ. Growth** - Beckenbach, et al. (JEE, 2012) - Novelty creating behavior and sectoral growth effects.
  - Market Structure** - Alemdar and Sirakaya (JEDC, 2003) - Computation of Stackelberg Equilibria.
  - Policy Making** - Arifovic, Bullard and Kostyshyna (EJ, 2013) - The effects of social learning in a monetary policy context.
    - The Taylor Principle is widely regarded as the necessary condition for stable equilibrium.
    - However, they show that it is not necessary for convergence to REE minimum state variable (MSV) equilibrium under genetic algorithm learning.

## Background

### Genetic Algorithm - The Learning Mechanism

- The genetic algorithm (GA), developed by John Holland (1970), is considered one of the evolutionary algorithms inspired by natural evolution with a core concept of “survival of the fittest”.
- The GA describes the evolutionary process of a population of genetic individuals with heterogeneous beliefs in response to the rules of nature.

## This Presentation

We introduce Arifovic (1994) as an example to investigate if the macro-level stability condition (the cobweb theorem) is necessary for a stable cobweb economy under GA.  
We would also like to see how to apply the genetic algorithm on a simple economic model.

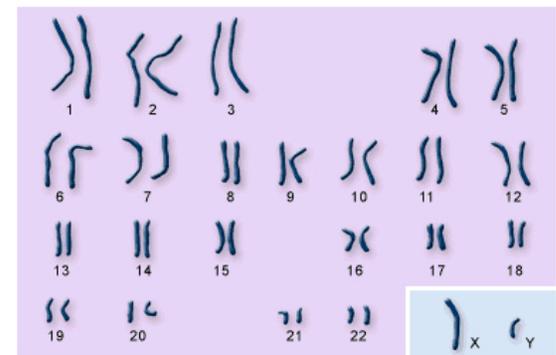

### Important terms:

- Genes, Chromosomes, and Populations
  - Chromosomes: Genetic individuals making heterogeneous decisions
  - Genes: Elements of a decision that a genetic individual makes
  - Population: A group of genetic individuals with heterogeneous decisions

## This Presentation

### Human Chromosomes - 23 pairs

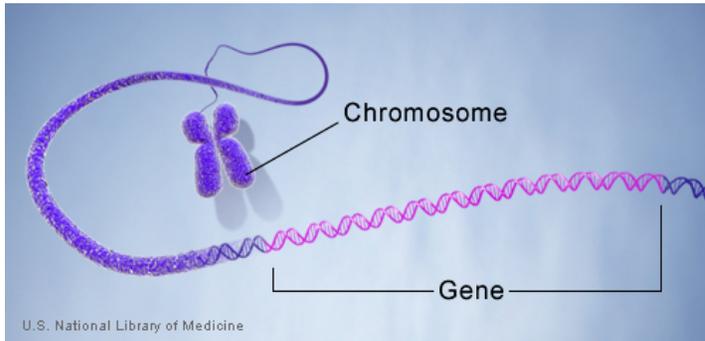

autosomes

sex chromosomes

## This Presentation

$\sum DNA = Gene$ , and  $\sum Gene = Chromosome$

## This Presentation

We introduce Arifovic (1994) as an example to investigate if the macro-level stability condition (the cobweb theorem) is necessary for a stable cobweb economy under GA.  
We would also like to see how to apply the genetic algorithm on a simple economic model.

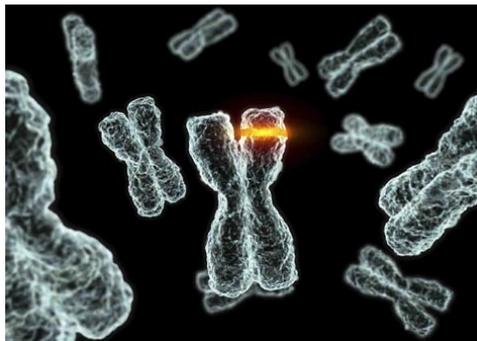

### Important terms:

- Reproduction, Mutation, and Crossover
  - Reproduction: An individual chromosome is copied from the previous population to a new population.
  - Mutation: One or more gene within an individual chromosome changes value randomly.
  - Crossover: Two randomly drawn chromosomes exchange parts of their genes.

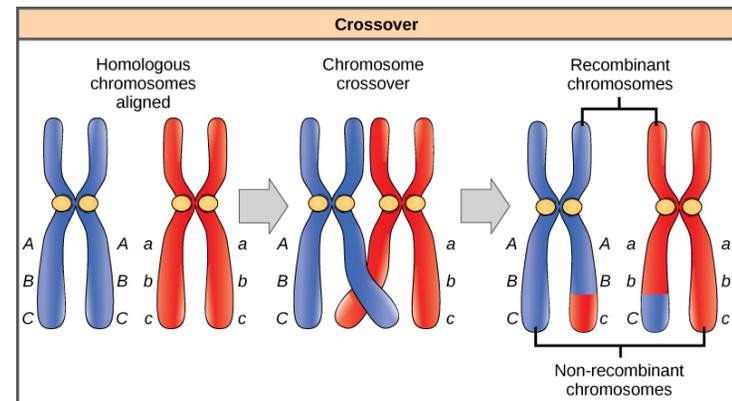

## This Presentation

### Genetic Mutation

## This Presentation

### Genetic Crossover

## Computational GA - Genes, Chromosomes, Population

The computational GA Environment can be presented as follows:

## The cobweb model- An Introduction

- It is a classic model which illustrates the dynamic process of prices in **agricultural** markets (Kaldor, 1934).
- Due to a lag between planting and harvesting, farmers cannot adjust the amount of agricultural output immediately to fulfill the demand in the market.
- As a result, farmers make their planting decisions today based on the predicted (or forecasted) price of the agricultural product in the next period.
- If farmers expect the price is high in the next period, they would like to plant more today to make more money tomorrow, and vice versa. (The Law of Supply.)

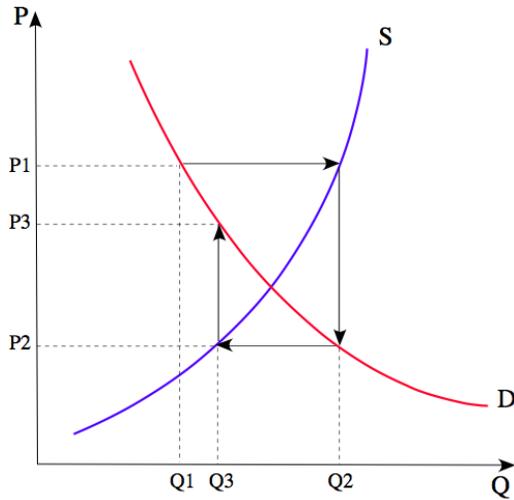

## The cobweb model- An Introduction

- Assuming that farmers “forecast” the price in the next period based on the price they observe today, that is,  $P_{t+1}^e = P_t$ .
- If the current price level  $P_t$  is high (and is higher than the equilibrium price  $P^*$ , which is assumed to be unknown for the farmers). It can be written as:  $P_{t=1} > P^*$ .
  - **At time  $t = 1$ ,** farmers would be very happy to plant more today so that they will have more output ( $Q_{t=2}$ ) which can be sold at the high price they expect in the next period.
  - **At time  $t = 2$ ,** since all farmers did the same in period 1, there are too much output available, which creates a “surplus” in the market, the price drops sharply at  $t = 2$  due to the excess supply, and it goes below the equilibrium:  $P_{t=2} < P^* < P_{t=1}$ .

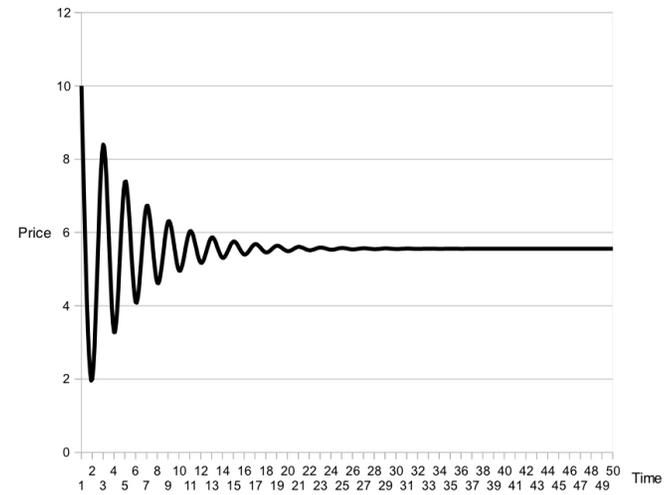

## The cobweb model- An Introduction

- **What would be the planting decision for the farmers at  $t = 2$ ?**
  - **At time  $t = 2$ ,** since they observe the today's price is low, they would expect the price will also be low in the next period ( $t = 3$ ). Therefore, they decide to plant less today...
  - **At time  $t = 3$ ,** since all farmers again are doing the exact same thing, the total output level turns out to be very low this time.  $Q_{s,t=3} < Q_{d,t=3}$  (**shortage!**). Therefore, the price jumps up!
- **What would be the planting decision for the farmers at  $t = 3$  now?**
  - **At time  $t = 3$ ,** since they observe the today's price is now high again, they would expect the price will also be high in the next period ( $t = 4$ ). Therefore, they decide to plant more today...
- This story keeps going...

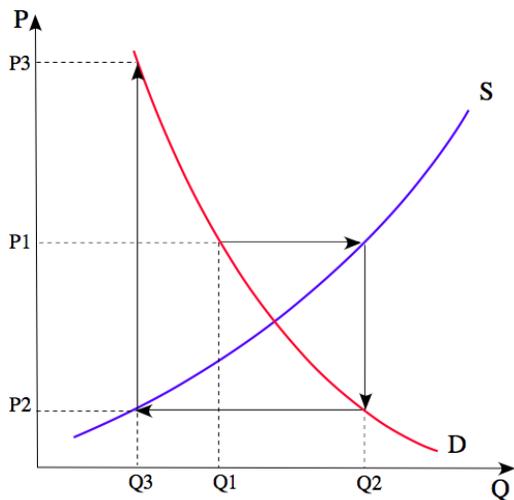

## The cobweb model- An Introduction

## The cobweb model- An Introduction

## The cobweb model- An Introduction

## The cobweb model - an mathematical illustration

- Arifovic (1994) assumes each firm  $i$  chooses a production level  $q_{it}$  to maximize its expected profit  $\pi_{it}^e$ .
- The cost function for firm  $i$  is:

$$C_{it} = aq_{it} + \frac{1}{2}bm q_{it}^2, \text{ where } a, b > 0.$$

- Given the expected price of the good  $P_t^e$  at time  $t$ , firm  $i$  is maximizing the following profit function:

$$\pi_{it}^e = P_t^e q_{it} - C_{it}(q_{it}) = P_t^e q_{it} - aq_{it} - \frac{1}{2}bm q_{it}^2.$$

- The first order condition for each firm  $i$  is:

$$P_t^e - a - bm q_{it} = 0 \Rightarrow q_{it} = \frac{P_t^e - a}{bm}.$$

## The cobweb model - an mathematical illustration

- Assuming all firms are identical so that  $q_{it} = q_t \forall i$ , the **aggregate supply** in the market is:

$$Q_t = \sum_{i=1}^m q_{it} = m q_t = \frac{P_t^e - a}{b}, \quad (1)$$

where  $m$  = number of firms in the market.

- Assuming that the **market demand** is a linear function:

$$P_t = \gamma - \theta Q_t, \quad (2)$$

where  $Q_t = \sum q_{it}$ .

- In equilibrium where (1)=(2), we can derive the following law of motion for the price level:

$$\frac{\gamma - P_t}{\theta} = \frac{P_t^e - a}{b} \Rightarrow P_t = \frac{\gamma b + a \theta}{b} - \frac{\theta}{b} P_t^e.$$

## The Cobweb Theorem and Simulation

	Stable Case ( $\frac{\theta}{b} < 1$ )	Unstable Case ( $\frac{\theta}{b} > 1$ )
Parameters		
$\gamma$	2.184	2.296
$\theta$	0.0152	0.0168
$a$	0	0
$b$	0.016	0.016
$m$	6	6
$P^*$	1.12	1.12
$Q^* = m q^*$	70	70

Table 12.1: Cobweb Model Parameters

## The Cobweb Theorem and Other Expectations Formations

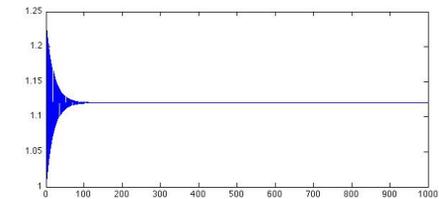

- The dynamics of the price level:

$$P_t = \frac{\gamma b + a \theta}{b} - \frac{\theta}{b} P_t^e.$$

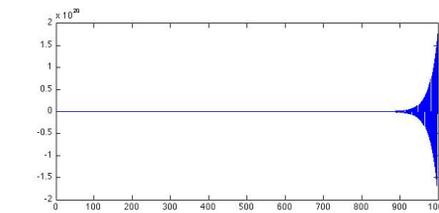

- According to Cobweb Theorem, the model is stable if  $\theta/b < 1$ , that is,  $\theta < b$ . However, the model is unstable if  $\theta/b > 1$ , that is,  $\theta > b$ .
- Arifovic discusses three types of expectations formations:
  - Static expectations (i.e.,  $P_t^e = P_{t-1}$ ):
    - The model is stable only if  $\theta/b < 1$ .
  - Simple adaptive expectations ( $P_t^e = \frac{1}{t} \sum_{s=0}^{t-1} P_s$ ):
    - The model is stable in **both** cases (Carlson, 1968).
  - Least squares learning ( $P_t^e = \beta_t P_{t-1}$ ,  $\beta_t$  = OLS coefficient):
    - The model is stable only if  $\theta/b < 1$  (Bray and Savin, 1986).

## The Cobweb Theorem and Simulation - Static

Static expectations (i.e.,  $P_t^e = P_{t-1}$ ):

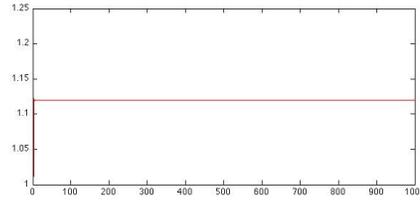

(Stable Case:  $\frac{\theta}{b} < 1$ )

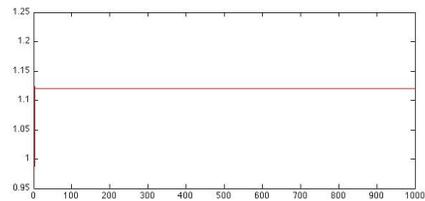

(Unstable Case:  $\frac{\theta}{b} > 1$ )

## The Cobweb Theorem and Simulation - Adaptive

Simple adaptive expectations ( $P_t^e = \frac{1}{t} \sum_{s=0}^{t-1} P_s$ ):

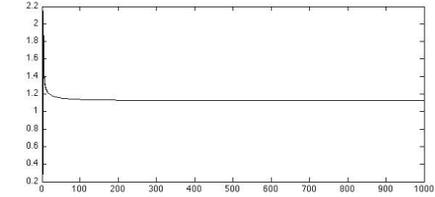

(Stable Case:  $\frac{\theta}{b} < 1$ )

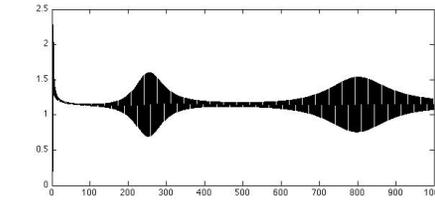

(Stable Case:  $\frac{\theta}{b} > 1$ )

## The Cobweb Theorem and Simulation - Least Squares

Least squares learning ( $P_t^e = \beta_t P_{t-1}$ ):

(Stable Case:  $\frac{\theta}{b} < 1$ )

(Unstable Case:  $\frac{\theta}{b} > 1$ )

## The Cobweb Theorem and GA

WHAT ABOUT THE GA LEARNING?

DOES THE COBWEB THEOREM HOLD UNDER THE GA?

## Outline

  - MATLAB Codes
  - Simulations
- 5 Concluding Remarks

## The Basic GA and Arifovic's New GA Operator

- Arifovic (1994) simulates the cobweb model based on three basic genetic operators in the GA simulations:
  - (1) reproduction, (2) mutation, and (3) crossover.
- She also introduces a new operator, called *election*, in the simulations.
- Election is an operator to "examine" the fitness of newly generated (or offspring) chromosomes and then compare them with their parent chromosomes.

## GA Learning Parameters

Parameters	Stable Case ( $\frac{\theta}{b} < 1$ )	Unstable Case ( $\frac{\theta}{b} > 1$ )
$\gamma$	2.184	2.296
$\theta$	0.0152	0.0168
$a$	0	0
$b$	0.016	0.016
$m$	6	6
$P^*$	1.12	1.12
$Q^* = mq^*$	70	70

Table 12.1: Cobweb Model Parameters

Set	1	2	3	4	5	6	7	8
Crossover rate: $\kappa$	0.6	0.6	0.75	0.75	0.9	0.9	0.3	0.3
Mutation rate: $\mu$	0.0033	0.033	0.0033	0.033	0.0033	0.033	0.0033	0.033

Table 12.2: Crossover and Mutation Rates

## New GA Operator - Arifovic (1991, 1994)

- The Rules of Election:
  - Both offspring chromosomes *are elected* to be in the new population at time  $t + 1$  if  $E_t \left( V \left( C_{it+1}^{offspring} \right) \right) > V \left( C_{it}^{Parent} \right)$ .
  - However, if only one new chromosome has a higher fitness value than their parents, the one with lower value will not enter the new population, but one of the parents with a higher values stays in the new population.
  - If both new chromosomes have lower values than their parents  $E_t \left( V \left( C_{it+1}^{offspring} \right) \right) < V \left( C_{it}^{Parent} \right)$ , they cannot enter but their parents stay in the new population.

Evolutionary Dynamics: Genetic Algorithm

## Conclusions

- Arifovic (1994) introduces the GA procedure as an alternative learning mechanism.
- This alternative learning mechanism mimics social behavior:
  - imitation, communication, experiment, and examination.
- Arifovic uses the GA simulated data to compare with the data generated in human-subject experiments (Wellford, 1989).
  - In an unstable case of the cobweb model, the divergent patterns *do not* happen under both GA learning and human-subject experiments.
  - Price and quantity fluctuate around the equilibrium in *basic* GA learning and human-subject experiments.

## Notations under the GA

- Chromosome  $C_i$  consists of a set of 0 and 1, where  $L$  is the length of a chromosome (the number of genes).
- $B^{max}(C_i) = 2^L - 1$  represents the maximum numerical value of a chromosome with the length  $L$ .

- For example, if  $L = 10$ , the maximum value of a chromosome:

$$B(1111111111) = 2^{10} - 1 = 1023.$$

- We can use the  $B$  operator to compute a numerical value of a chromosome (e.g.,  $C_i = 0100101110$ ):

$$\begin{aligned} B(0100101110) &= 0 \times 2^9 + 1 \times 2^8 + 0 \times 2^7 + 0 \times 2^6 + \\ &1 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + \\ &1 \times 2^1 + 0 \times 2^0 = 302. \end{aligned}$$

## Notations under the GA

- Assume that there are  $M = 8$  genetic individuals. For  $L = 10$ , we can generate an initial genetic population  $P_0$  in an  $M \times L$  matrix (that is,  $8 \times 10$  matrix):
- For example:

$$P_0 = \begin{matrix} 0100101110 \\ 1110101010 \\ 0101110100 \\ 0100001010 \\ 1110101000 \\ 0101101101 \\ 1100101010 \\ 0100011100 \end{matrix}$$

## Notations under the GA

- According to the problem of profit maximization, if  $a = 200$ ,  $b = 4$ , and  $e = 40$ , then  $q^* = 20$ .
- In this case, the maximum value of a chromosome can be too large for this problem ( $B^{max} = 1023$ ).
- We can define a maximum economic value for a chromosomes  $V(C_i)$  based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i),$$

where  $V(C_i) \in [0, U^{max}]$  for  $B(C_i) \in [0, B^{max}]$ , and  $U^{max}$  is the maximum economic value in the problem.

## Notations under the GA

- An economic value for a chromosomes  $V(C_i)$  based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i).$$

- For example, given the maximum output level is  $U^{max} = 100$ , and  $C_i = 0100101110$  (i.e.,  $B(C_i) = 302$ ), we can calculate the output level for firm  $i$ :

$$q_i = V(C_i) = \frac{100}{1023} \times 302 = 29.52 \approx 30.$$

## Notations under the GA

- Is firm  $i$  doing a good job? We need to evaluate firm  $i$  using a fitness function  $F(C_i)$ .
- The profit function is used as the fitness function in this case:

$$\begin{aligned} F(C_i) &= \pi(V(C_i)) \\ &= \pi(q_i) = (a - bq_i)q_i - (d + eq_i). \end{aligned}$$

- In this case,

$$\begin{aligned} F(C_i) &= \pi(V(C_i)) \\ &= \pi(29.52) = (200 - 4(29.52))(29.52) - (50 + 40(29.52)) \\ &= 1187.48. \end{aligned}$$

- The maximum profit is (for  $q^* = 20$ ):

$$F^{max} = \pi(q^*) = \pi(20) = 1550.$$

## The GA Operators

### Reproduction ⇒ Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
  - Higher fitness value ⇒ higher probability of being drawn to the new population.

- The relative fitness function is:

$$R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^M F(C_{m,t})},$$

where  $\sum_{i \in M} R(C_{i,t}) = 1$ .

- The relative fitness value  $R(C_{i,t})$  gives us the probability chromosome  $i$  is copied to the new population at time  $t+1$ .

## The GA Operators

### Reproduction

- What if  $F(C_{i,t})$  is negative for some firm  $i$ ? (a negative profit?)
- Goldberg (1989) proposes a scaled relative fitness function:

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^M [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^M F(C_{m,t}) + MA},$$

where  $A$  is a constant such that  $A > -\min_{C_i \in P_t} F(C_{i,t})$ .

## The GA Operators

### Crossover

- A crossover point will be randomly chosen to separate each chromosome into two sub-strings.
- Two “offspring” chromosomes will be formed by swapping the right-sided parents’ substrings with probability  $\kappa$ .

## The GA Operators

### Crossover

Therefore, there are  $20 - 1 = 19$  possible positions for crossover.  
We randomly pick a position for each pair of chromosomes.

Break the population into 3 groups.  
Randomly pick a position between Position 1 and Position 19

## Defining Parameter Values

```

6      %Initial Population Parameters:
7      %ind = number of agents(chromosomes) in a population
8      %bit = number of genes in each agent(chromosome)
9      %Umax = the upper bound of the real economic values
10     %epsilon = the value for the scaled relative fitness
11     %kappa = Probability of Crossover
12     %mu = Probability of Mutation
13     %time = number of generations(simulations)
14     ind = 200;
15     bit = 32;
16     Umax = 50;
17     epsilon = .1;
18     kappa = 0.6; %Arifovic (1994)
19     mu = 0.0033; %Arifovic (1994)
20     time = 500;
21
22     %Profit function parameters
23     % Demand function: p = a - bq
24     % Cost function: c = d + eq
25     % Profit function: profit = (a-bq)q - (d+eq)q
26     % Optimal level of output: q* = (a-e)/2b
27     a = 200;
28     b = 4;
29     d = 50;
30     e = 40;
31     qstar = (a-e)/(2*b);
    
```

## Creating an Initial Population

```

66     %Value Function and Definitions
67     Bmax = (2.^ bit) - 1;
68     m = ind;
69     n = bit;
70
71     %Generate the Initial Population: "gen"
72     gen = rand(m,n);
73     for i=1:m
74         for j=1:n
75             if gen(i,j)<.5;
76                 gen(i,j)=0;
77             else
78                 gen(i,j)=1;
79             end
80         end
81     end
    
```

## Converting Binary Value into Numerical Value

```

87     %Calculate the real value of each chromosome: "BC"
88     m2 = 2 * ones(n,1);
89     for i=1:n
90         m2(i,1)=m2(i,1).^(n-i);
91     end
92
93     BC = ones(m,1);
94     for i=1:m
95         BC(i,1)=gen(i,:) * m2; %Converting Binary # to Decimal # for each i
96     end
97
    
```

- For example,

$$\begin{aligned}
 B(0100101110) &= 0 \times 2^9 + 1 \times 2^8 + 0 \times 2^7 + 0 \times 2^6 + \\
 & 1 \times 2^5 + 0 \times 2^4 + 1 \times 2^3 + 1 \times 2^2 + \\
 & 1 \times 2^1 + 0 \times 2^0 = 302.
 \end{aligned}$$

## Notations under the GA

- An economic value for a chromosomes  $V(C_i)$  based on the following value function:

$$V(C_i) = \frac{U^{max}}{B^{max}} \times B(C_i).$$

- For example, given the maximum output level is  $U^{max} = 100$ , and  $C_i = 0100101110$  (i.e.,  $B(C_i) = 302$ ), we can calculate the output level for firm  $i$ :

$$q_i = V(C_i) = \frac{100}{1023} \times 302 = 29.52 \approx 30.$$

## Notations under the GA

- Is firm  $i$  doing a good job? We need to evaluate firm  $i$  using a fitness function  $F(C_i)$ .
- The profit function is used as the fitness function in this case:

$$\begin{aligned} F(C_i) &= \pi(V(C_i)) \\ &= \pi(q_i) = (a - bq_i)q_i - (d + eq_i). \end{aligned}$$

- In this case,

$$\begin{aligned} F(C_i) &= \pi(V(C_i)) \\ &= \pi(29.52) = (200 - 4(29.52))(29.52) - (50 + 40(29.52)) \\ &= 1187.48. \end{aligned}$$

- The maximum profit is (for  $q^* = 20$ ):

$$F^{max} = \pi(q^*) = \pi(20) = 1550.$$

## The GA Operators

### Reproduction $\Rightarrow$ Evolutionary Dynamics

- Reproduction is a genetic operator where an individual chromosome is copied from the previous population to a new population.
- The probability of being drawn for each chromosome is calculated based on the fitness value.
  - Higher fitness value  $\Rightarrow$  higher probability of being drawn to the new population.

- The relative fitness function is:

$$R(C_{i,t}) = \frac{F(C_{i,t})}{\sum_{m=1}^M F(C_{m,t})},$$

where  $\sum_{i \in M} R(C_{i,t}) = 1$ .

- The relative fitness value  $R(C_{i,t})$  gives us the probability chromosome  $i$  is copied to the new population at time  $t+1$ .

## The GA Operators

### Reproduction

```

122 %This is the code for Reproduction
123 - norm_fit = SC
124 - selected = rand(size(SC))
125 - sum_fit = 0;
126 - for i=1:length(SC)
127 -     sum_fit = sum_fit + norm_fit(i)
128 -     index = find(selected < sum_fit)
129 -     selected(index) = i * ones(size(index))
130 - end
131 - gen = gen(selected, :)
132
    
```

Goldberg (1989) proposes a scaled relative fitness function:

$$S(C_{i,t}) = \frac{F(C_{i,t}) + A}{\sum_{m=1}^M [F(C_{m,t}) + A]} = \frac{F(C_{i,t}) + A}{\sum_{m=1}^M F(C_{m,t}) + MA},$$

where  $A$  is a constant such that  $A > -\min_{C_i \in P_t} F(C_{i,t})$ .

## Concluding Remarks

- Why do we use the GA (or ABM in general) for political science / economics research??
  - Some models are mathematically intractable (we cannot find a closed-form equilibrium).
  - No strong assumptions imposed (such as, efficient markets, rational agents, representative agent hypothesis).
  - It allows non-linearity in a theoretical model.
  - It is relatively easier to capture equilibrium (equilibria) in a multi-national, multi-sector model.
